# The Anatomy of a Large-Scale Hypertextual Web Search Engine

Sergey Brin and Lawrence Page

Computer Science Department, Stanford University, Stanford, CA 94305, USA sergey@cs.stanford.edu and page@cs.stanford.edu

### **Abstract**

In this paper, we present Google, a prototype of a large-scale search engine which makes heavy use of the structure present in hypertext. Google is designed to crawl and index the Web efficiently and produce much more satisfying search results than existing systems. The prototype with a full text and hyperlink database of at least 24 million pages is available at http://google.stanford.edu/ To engineer a search engine is a challenging task. Search engines index tens to hundreds of millions of web pages involving a comparable number of distinct terms. They answer tens of millions of queries every day. Despite the importance of large-scale search engines on the web, very little academic research has been done on them. Furthermore, due to rapid advance in technology and web proliferation, creating a web search engine today is very different from three years ago. This paper provides an in-depth description of our large-scale web search engine -- the first such detailed public description we know of to date. Apart from the problems of scaling traditional search techniques to data of this magnitude, there are new technical challenges involved with using the additional information present in hypertext to produce better search results. This paper addresses this question of how to build a practical large-scale system which can exploit the additional information present in hypertext. Also we look at the problem of how to effectively deal with uncontrolled hypertext collections where anyone can publish anything they want.

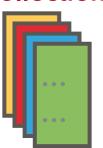

### Keyword

World Wide Web, Search Engines, Information Retrieval, PageRank, Google

### 1. Introduction

(Note: There are two versions of this paper -- a longer full version and a shorter printed version. The full version is available on the web and the conference CD-ROM.)

The web creates new challenges for information retrieval. The amount of information on the web is growing rapidly, as well as the number of new users inexperienced in the art of web research. People are likely to surf the web using its link graph, often starting with high quality human maintained indices such as Yahoo! or with search engines. Human maintained lists cover popular topics effectively but are subjective, expensive to build and maintain, slow to improve, and cannot cover all esoteric topics. Automated search engines that rely on keyword matching usually return too many low quality matches. To make matters worse, some advertisers attempt to gain people's attention by taking measures meant to mislead automated search engines. We have built a large-scale search engine which addresses many of the problems of existing systems. It makes especially heavy use of the additional structure present in hypertext to provide much higher quality search results. We chose our system name, Google, because it is a common spelling of googol, or 10<sup>100</sup> and fits well with our goal of building very large-scale search

# **INDEXING**

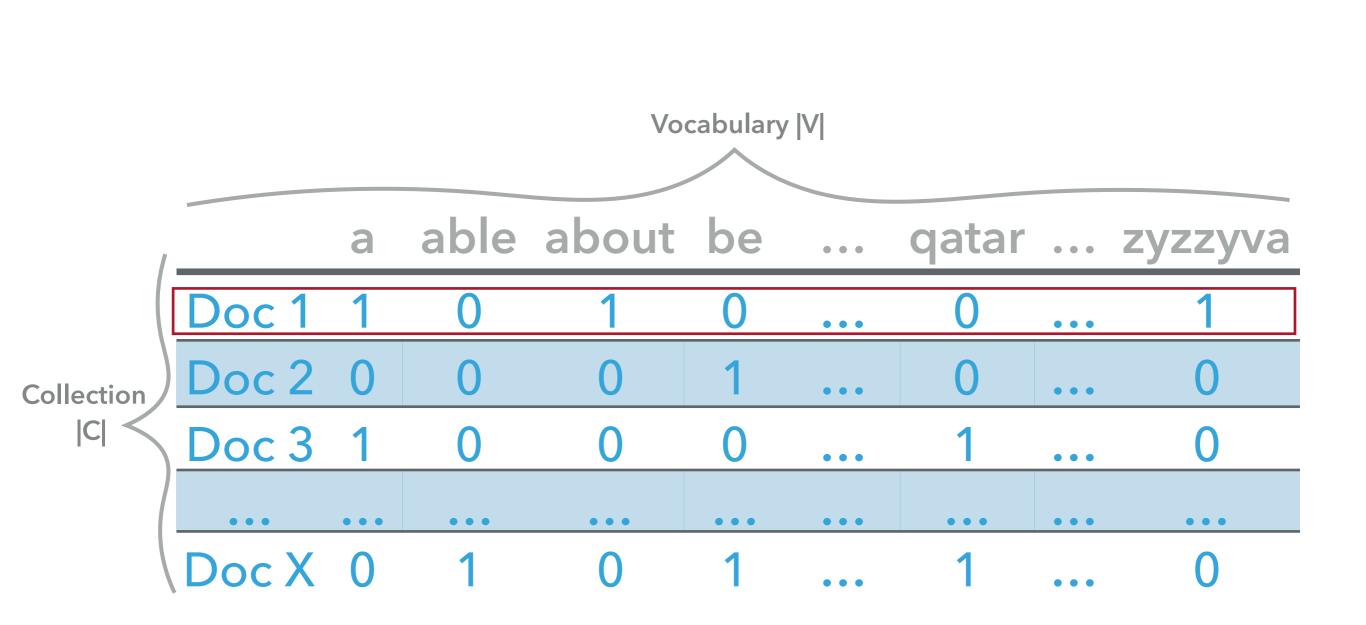

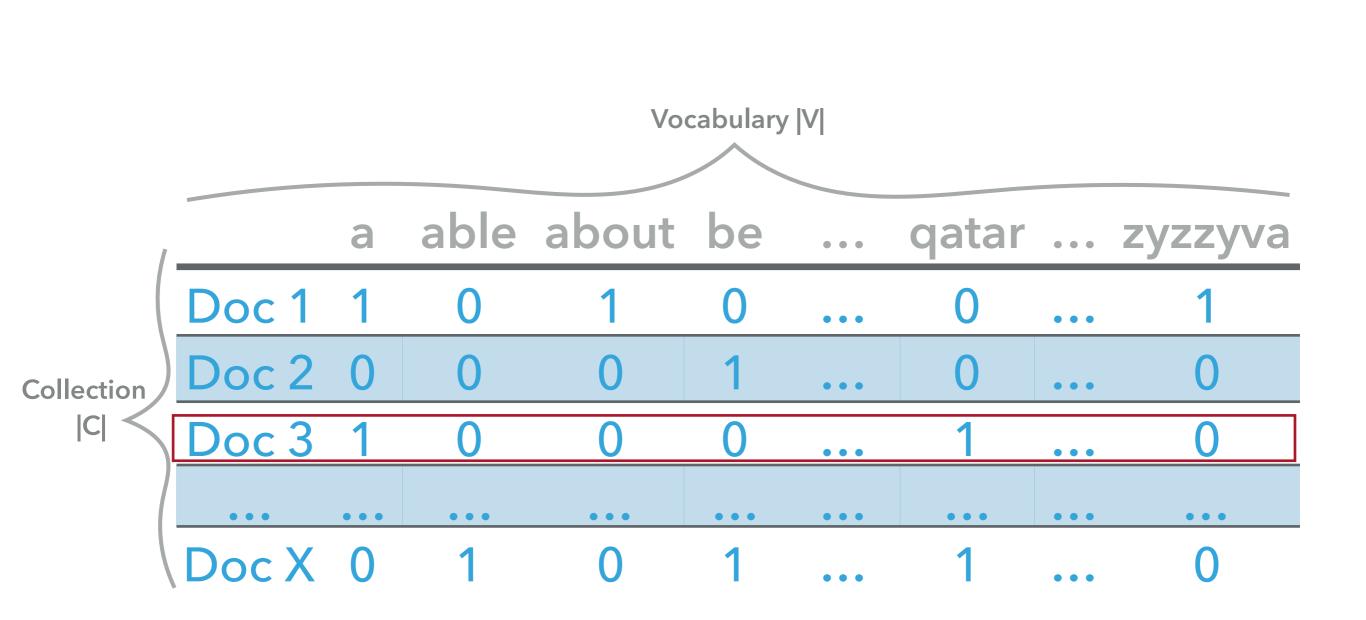

zyzzyva

zyzzyva

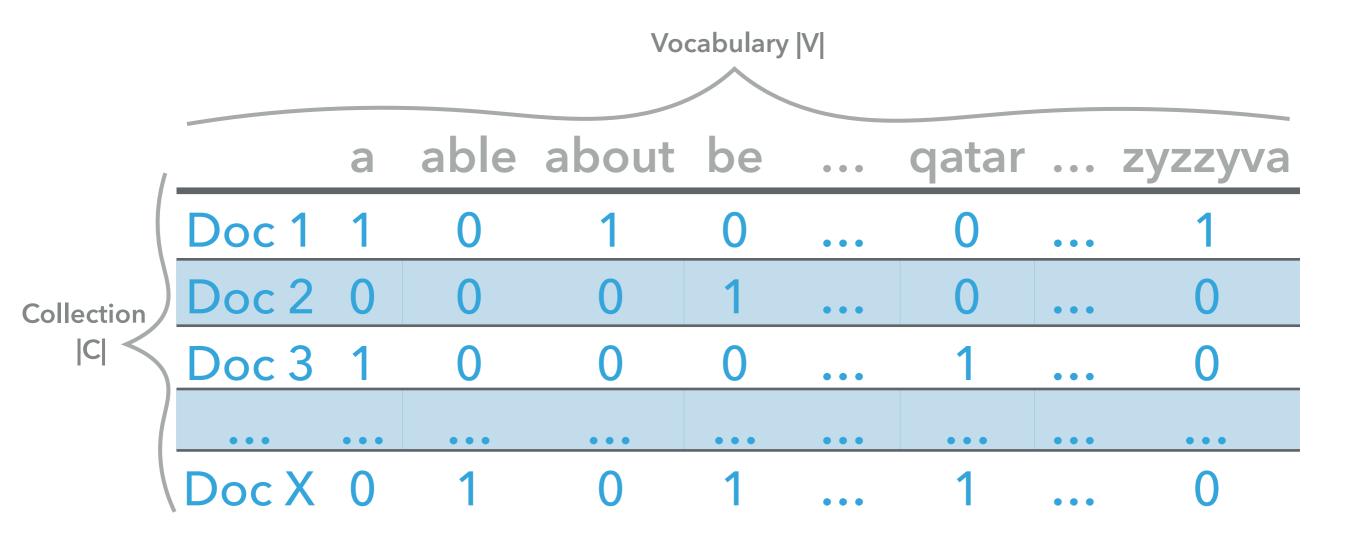

a qatar

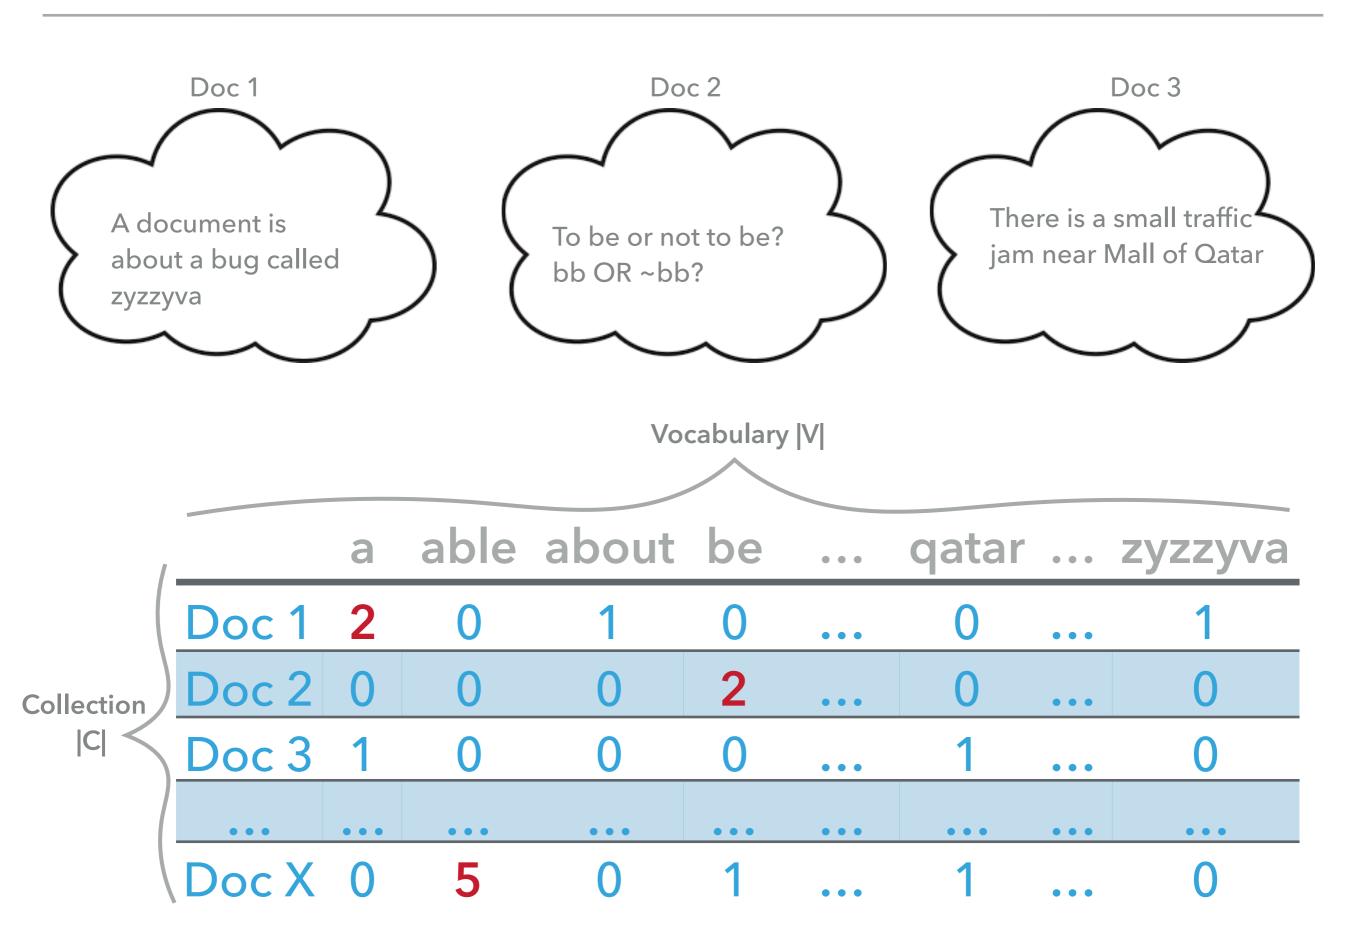

- Invented first
- Useful simplification (almost never used why?)

- Position and frequency are ignored
- Can we do something for the frequency?

	Vocabulary  V								
		a	able	about	be	• • •	qatar	• • •	zyzzyva
Collection  C	Doc 1	1	0	1	0	• • •	0	•••	1
	Doc 2	0	0	0	1	• • •	0	• • •	0
	Doc 3	1	0	0	0	• • •	1	• • •	0
	• • •	• • •	• • •	• • •	• • •	• • •	• • •	• • •	• • •
	\Doc X	0	1	0	1	• • •	1	•••	0

# FREQUENCY-BASED FULL-TEXT REPRESENTATION

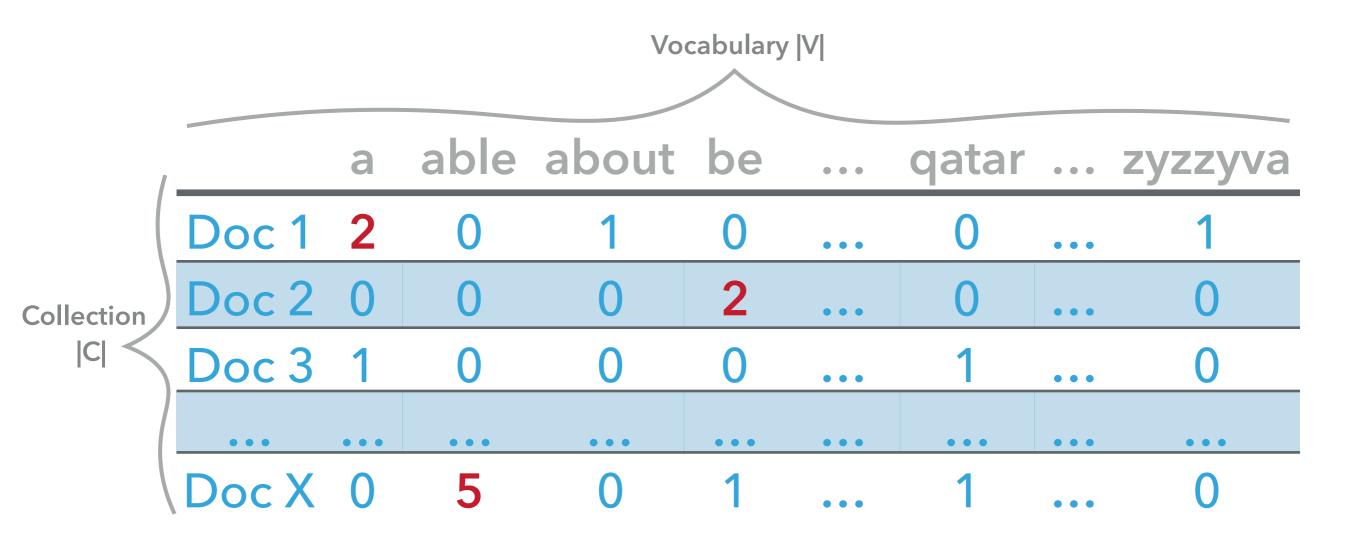

- More effective for search, but...
- > Still very very large table... 90% are zeros...

#### FREQUENCY-BASED FULL-TEXT REPRESENTATION

How to process a query: "qatar doha" ?

## **QUERY MATCHING**

```
result = []
for query_token in query:
    for document in collection:
        for document_token in document:
            if query_token == document_token:
                 result += [document]
                 break
```

Vocabulary |V|

		a	able	about	be	• • •	qatar	• • •	zyzzyva
	Doc 1	2	0	1	0	• • •	0	• • •	1
	Doc 2	0	0	0	2	• • •	0	• • •	0
	Doc 3	1	0	0	0	• • •	1	• • •	0
	• • •	• • •	• • •	• • •	• • •	• • •	• • •	• • •	• • •
	Doc X	0	5	0	1	• • •	1	•••	0

## **QUERY MATCHING**

Most of them will not match

Time complexity: O(|q| \* C \* |D|)

a able about be ... qatar ... zyzzyva

| Doc 1 2 0 1 0 ... 0 ... 1 |
| Doc 2 0 0 0 2 ... 0 ... 0 |
| Doc 3 1 0 0 0 ... 1 ... 0 |
| Doc X 0 5 0 1 ... 1 ... 0

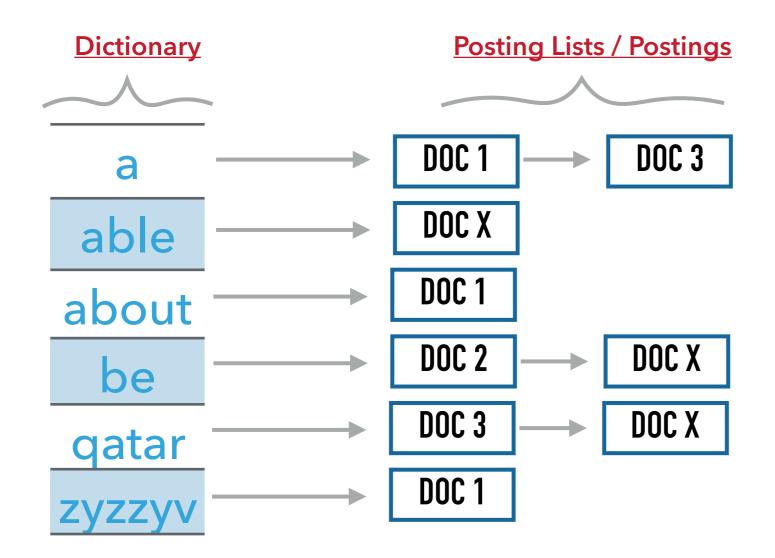

Vocabulary |V|

#### **SOLUTION: INVERTED INDEX**

#### **Inverted Index**

Look-up table (hash table) for each word in vocabulary

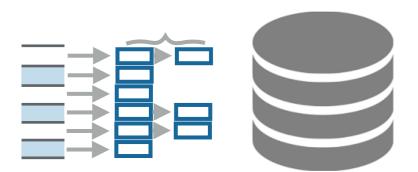

Time complexity: O(|q| \* |L|) |L| is the average length of posting list

#### **Inverted Index**

#### **INVERTED INDEX STRUCTURES**

Dictionary: medium size

- (largely) stays in memory in large search engines
- Usually implemented with Hash table, B-tree, trie...
- Postings: very large size
  - Stays on disk (but not for our homework)
  - Might need compression
  - Usually a lot of statistics are kept there: docld, term freq, term position...

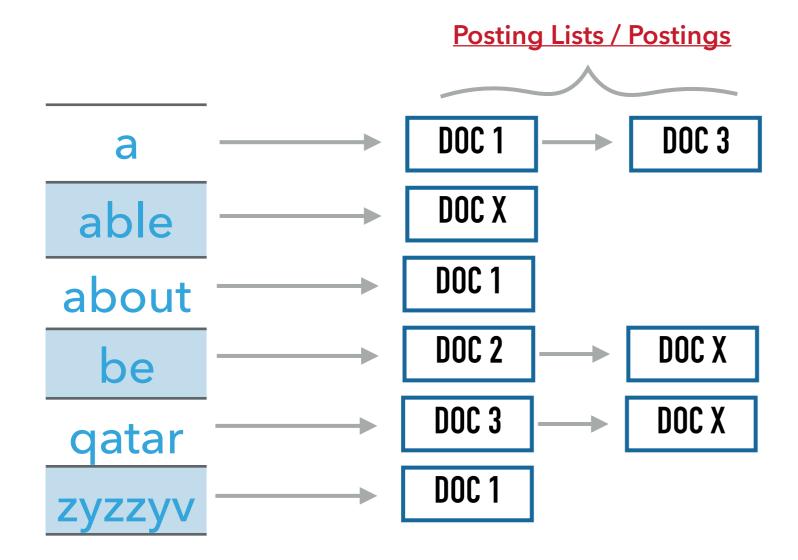

# BOOLEAN SEARCH

## **SEARCHING WITH INVERTED INDEX**

a qatar  $\rightarrow$ 

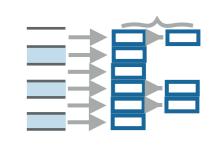

#### **Inverted Index**

#### **Inverted Index**

#### SEARCHING WITH INVERTED INDEX

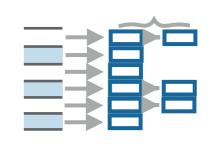

- Query syntax and operators:
  - doha OR qatar; doha AND qatar; doha NOT qatar
- Same preprocessing procedures as on indexed documents
  - lower case/upper case
  - tokenization
  - stemming
  - stopwords removal

## **SEARCHING WITH INVERTED INDEX**

a qatar ->

- How to:
  - Look up each term in the dictionary
  - Retrieve their posting lists
  - Operations:
    - AND: intersection of posting lists
    - OR: union of posting lists
    - NOT: difference of posting lists

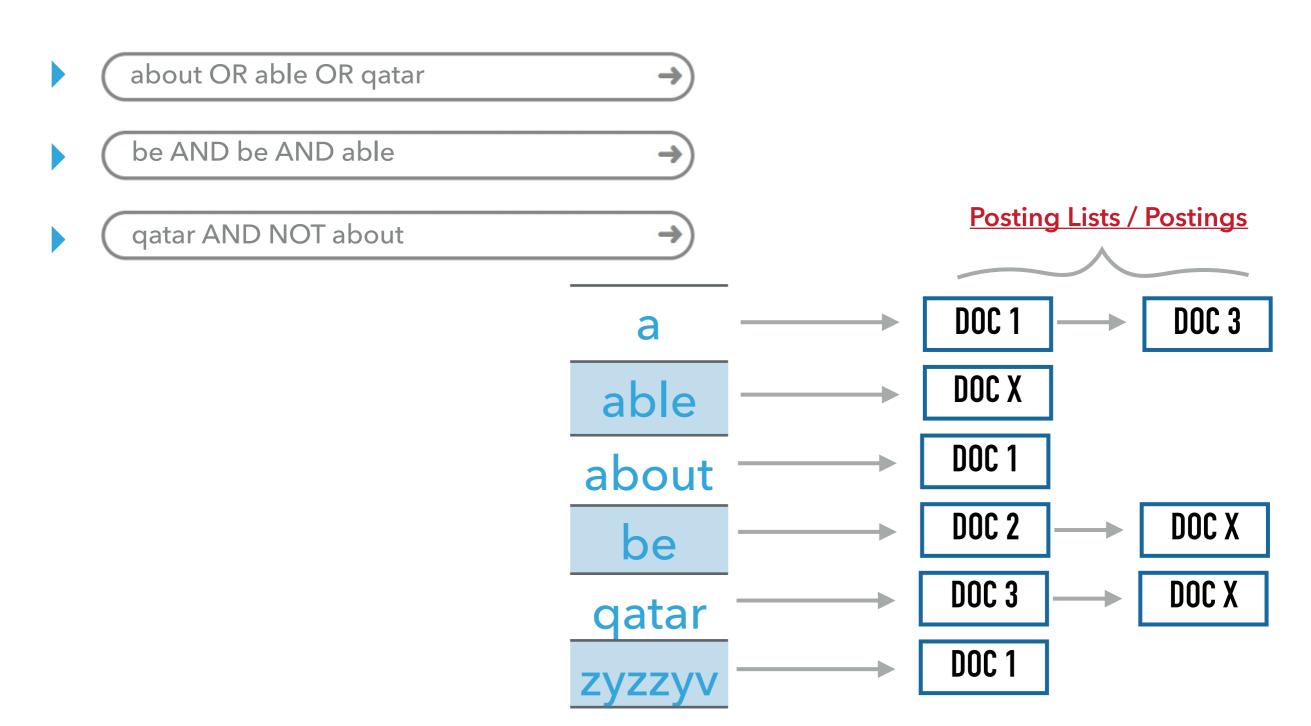

**Inverted Index** 

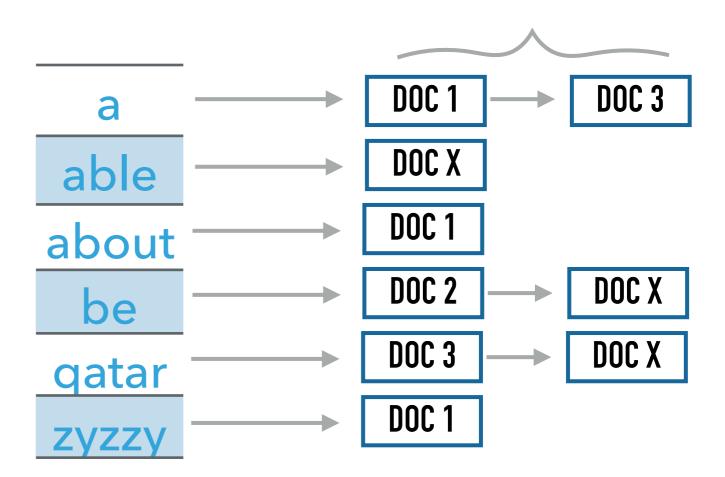

#### SEARCHING WITH INVERTED INDEX

**Example:** 

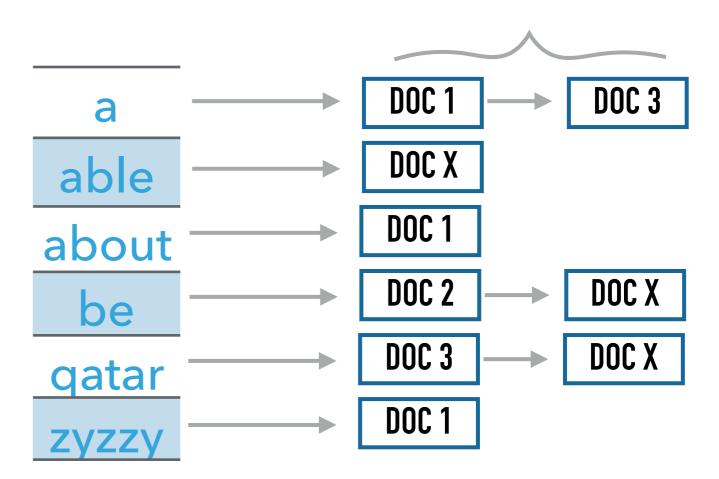

What would be necessary to be able to deal with phrase queries? Ex. "barack obama", "search engines", "new york"

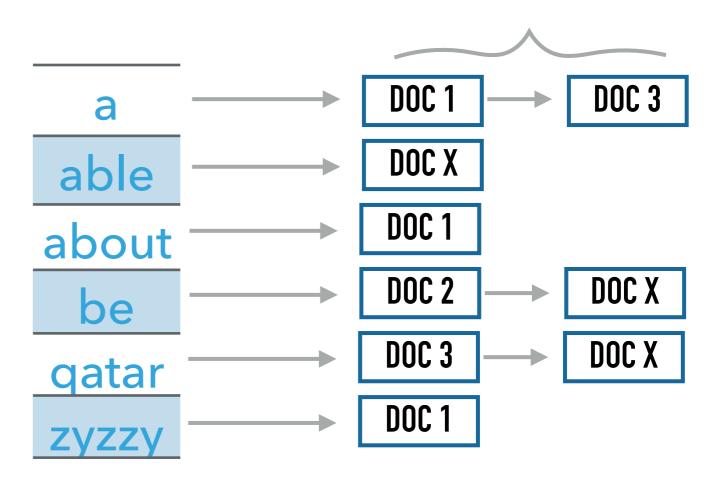

What would be necessary to be able to deal with phrase queries? Ex. "barack obama", "search engines", "new york"

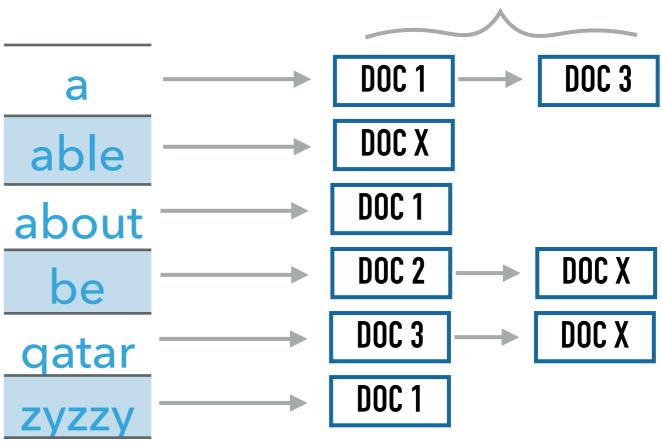

#### Save term position in document postings

- What would be necessary to be able to deal with phrase queries? Ex. "barack obama", "search engines", "new york"
  - T2.pos T1.pos = 1 in the same document

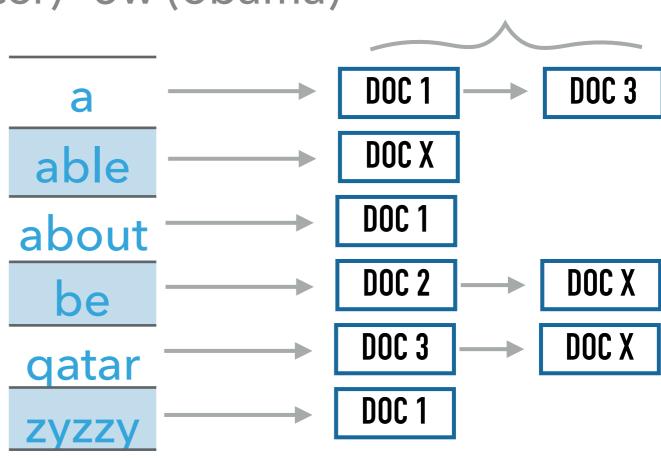

- What would be necessary to be able to deal with phrase queries? Ex. "barack obama", "search engines", "new york"
  - ▶ T2.pos T1.pos = 1 in the same document
- ► How about proximity: (cancer)~5w (obama)

- What would be necessary to be able to deal with phrase queries? Ex. "barack obama", "search engines", "new york"
  - T2.pos T1.pos = 1 in the same document
- ► How about proximity: (cancer)~5w (obama)
  - ▶ |T1.pos T2.pos| < k

**NOT NECESSARY IN YOUR** 

**HOMEWORK ASSINGMENTS** 

#### **IMPLEMENTATION NOTE**

- Boolean Search is quite simple to implement
  - Sets are used to do the main operation
- It is necessary to have a query language:
  - term OR term AND term NOT (term OR term)
  - Processing the query is harder now
  - Normal Formulas can help you doing that

#### PIECES OF CODE FOR QUERY PROCESSING IN PYTHON

```
from sympy.logic.boolalg import to_dnf

query = "(qatar | qatari) & doha & ~(arabic | desert)"

processed = to_dnf(query)

print processed
```

Or(And(Not(arabic), Not(desert), doha, qatar), And(Not(arabic), Not(desert), doha, qatari))

There is an AND: And(Not(arabic), Not(desert), doha, gatari)

```
from sympy.logic import And, Or, Not
from sympy.core.symbol import Symbol

for part in processed.args:
    if type(part) is And:
        print "There is an AND:", part
    if type(part) is Or:
        print "There is a Or:", part
    if type(part) is Not:
        print "There is a Or:", part
    if type(part) is Symbol:
        print "This is a symbol:", part
There is an AND: And(Not(arabic), Not(desert), doha, gatar)
```

## **BONUS PART**

# SPELLING

## SPELLING CORRECTION

- How to find and deal with misspelled queries:
  - "barck obama" -> did you mean "barack obama"?

## **SPELLING CORRECTION**

- How to find and deal with misspelled queries:
  - "barck obama" -> did you mean "barack obama"?

- Out of English dictionary?
- Look at the size of posting lists for "barck"?
- Look at past query logs

## **SPELLING CORRECTION**

- ▶ Edit distance:
  - What is the minimal number of additions/modifications/deletions do I need to do from "barck obama" to "barack obama"?
  - Issue new query and see if result list increased

- Possibilities to apply many heuristics:
  - query context: flew form hamad airport -> flew from hamad airport
  - phonetic similarity: where, wear; to, two, too; ...
    - Phonetic hasing similar sounding terms hash to same value
